

Lab Report – EE-170L Computer Programming (Lab 12)

NAME	Zakirullah
Reg.no	0909
SEMESTER	2nd
LAB	12
DATE	12/5/2026

Objectives

- To understand computer memory and variables.
- To learn pointer declaration in C++.
- To apply referencing (&) and dereferencing (*) operators.
- To explore pointer arithmetic with arrays.

Theory

1. Computer Memory

- Memory is divided into **bytes**, each with a unique **address**.
- A variable reserves a block of memory depending on its type (e.g., `int` = 4 bytes on 32-bit systems).
- The compiler maps variable names to memory addresses.

2. Pointers

- A pointer is a variable that stores the address of another variable.
- Declaration syntax:

`dataType *ptr;`

- Referencing operator (&) → gives the address of a variable.
- Dereferencing operator (*) → accesses or modifies the value stored at the address.

3. Pointer Arithmetic

- Pointers can be incremented or decremented to move across memory addresses.
- Useful for traversing arrays without using indices

Lab Tasks

Task 1: Pointer Declaration and Initialization

```
#include <iostream>    //tells the compiler to include input output stream library

using namespace std;   // tells the compiler to include standard namespace

int main() {           // main function begins from here

    int num = 25;       // declare integer variable

    int *ptr;           // declare pointer to int

    ptr = &num;         // store address of num in ptr

    cout << "Value of num: " << num << endl;    // display num directly

    cout << "Value via ptr: " << *ptr << endl;   // display value using pointer

    cout << "Address of num: " << ptr << endl;   // display address stored in ptr

    return 0;           // end program

}
```

Task 2: Pointer Arithmetic with Arrays

```
#include <iostream>    //tells the compiler to include input output stream library

using namespace std;   // tells the compiler to include standard namespace
```

```
int main() {                                     // main function begins from here

    int numbers[5] = {10, 20, 30, 40, 50};      // array declaration and initialization

    int *ptr;                                    // declare pointer

    ptr = numbers;                              // point to first element of array

    cout << "Array elements using pointer:" << endl; // output prompt

    for(int i = 0; i < 5; i++) {                // for loop that runs 5 times

        cout << *(ptr + i) << " ";            // access elements using pointer arithmetic

    }

    cout << endl;                               // moves compiler to next line

    return 0;                                   // end program

}
```

Results

- Learned how pointers store addresses of variables.
- Demonstrated dereferencing to access values through pointers.
- Applied pointer arithmetic to traverse arrays without indices.
- Observed how memory addresses change as the pointer moves across array elements.
